Chronic obstructive pulmonary disease mortality and prevalence: the associations with smoking and poverty—a BOLD analysis

Peter Burney, Anamika Jithoo, Bernet Kato, Christer Janson, David Mannino, Ewa Nižankowska-Mogilnicka, Michael Studnicka, Wan Tan, Eric Bateman, Ali Koçabas, William M Vollmer, Thorarrin Gislason, Guy Marks, Parvaiz A Koul, Imed Harrabi, Louisa Gnatiuc, Sonia Buist, for the Burden of Obstructive Lung Disease (BOLD) Study

ABSTRACT

Background Chronic obstructive pulmonary disease (COPD) is a commonly reported cause of death and associated with smoking. However, COPD mortality is high in poor countries with low smoking rates. Spirometric restriction predicts mortality better than airflow obstruction, suggesting that the prevalence of restriction could explain mortality rates attributed to COPD. We have studied associations between mortality from COPD and low lung function, and between both lung function and death rates and cigarette consumption and gross national income per capita (GNI).

Methods National COPD mortality rates were regressed against the prevalence of airflow obstruction and spirometric restriction in 22 Burden of Obstructive Lung Disease (BOLD) study sites and against GNI, and national smoking prevalence. The prevalence of airflow obstruction and spirometric restriction in the BOLD sites were regressed against GNI and mean pack years smoked.

Results National COPD mortality rates were more strongly associated with spirometric restriction in the BOLD sites (<60 years: men r_s=0.73, p=0.0001; women r_s=0.90, p<0.0001; 60+ years: men r_s=0.63, p=0.0022; women r_s=0.37, p=0.1) than obstruction (<60 years: men r_s=0.28, p=0.20; women r_s=0.17, p=0.46; 60+ years: men r_s=0.28, p=0.23; women r_s=0.22, p=0.33). Obstruction increased with mean pack years smoked, but COPD mortality fell with increased cigarette consumption and rose rapidly as GNI fell below US$15 000. Prevalence of restriction was not associated with smoking but also increased rapidly as GNI fell below US$15 000.

Conclusions Smoking remains the single most important cause of obstruction but a high prevalence of restriction associated with poverty could explain the high COPD mortality in poor countries.

INTRODUCTION

Chronic obstructive pulmonary disease (COPD) is now the third most common cause of death in the world. COPD is defined in terms of airflow obstruction and operationalised as a low ratio of forced expiratory volume in 1 s (FEV_1) to forced vital capacity (FVC). By far the strongest risk factors for airflow obstruction are smoking and exposure to environmental tobacco smoke, but many areas of the world with high mortality rates from COPD have low consumption of tobacco. The distribution of death from COPD in the UK is not the same as that of lung cancer, the disease most strongly associated with tobacco consumption, but is more closely associated with low social status and poverty.

A low FEV_1 is associated with increased mortality, including a high mortality from cardiovascular disease, but there is also evidence of an association with a low FVC, a measure correlated with the spirometric restriction and not with airflow obstruction. We examined the relation of national mortality rates from COPD, as recorded by the global health observatory, with the prevalence of airflow obstruction and spirometric restriction in 22 Burden of Obstructive Lung Disease (BOLD) study sites, and with the prevalence of smoking and poverty. We
also used the BOLD data from 22 sites to describe the distribution of airflow obstruction (FEV1/FVC less than the lower limit of normal (<LLN)) and spirometric restriction (FVC<LLN) across these sites and their relation with smoking prevalence and poverty stratified by sex.

METHODS
The design and rationale for the BOLD study, the characteristics of samples and the prevalence of COPD in 14 sites have been reported elsewhere.\textsuperscript{11–13} Data collection from an additional eight sites has been completed since these earlier publications and added to the dataset for these analyses. The study population comprised non-institutionalised people aged 40 years and older stratified by sex.

BOLD sites are selected to represent the Global Burden of Disease regions, giving greater weight to larger regions but still ensuring at least two sites in most regions. Within regions, selection of sites is largely dependent on the availability of suitable collaborators, but sites are asked to sample from substantial populations of over 250 000 from predefined administrative areas to avoid highly exceptional populations.

Response rates were defined as the number of responders (those who completed the core questionnaire and post-bronchodilator spirometry) divided by the total number of individuals contacted. Cooperation rates were defined as the number of responders divided by the total number of responders plus active refusers.

Lung function, including FEV\textsubscript{1} and FVC, was measured using the ndd EasyOne Spirometer (ndd Medizintechnik AG, Zurich, Switzerland), before and 15 min after inhaling salbutamol (200 μg) from a metered dose inhaler through a spacer. Spiromgrams were reviewed by the BOLD Pulmonary Function Reading Centre, and assigned a quality score based on acceptability and reproducibility criteria from the American Thoracic Society (ATS) and European Respiratory Society (ERS).\textsuperscript{14} Spirometry technicians at BOLD sites were certified before data collection, received regular feedback on quality and were required to maintain a prespecified quality standard.

Outcome measures were airflow obstruction, defined as a post-bronchodilator FEV\textsubscript{1}/FVC ratio below the LLN for age and sex,\textsuperscript{15} based on reference equations for Caucasians derived from the third US National Health and Nutrition Examination Survey,\textsuperscript{16} and spirometric restriction defined as a post-bronchodilator FVC below the LLN for height, age and sex, based on the same reference population.

Information on respiratory symptoms, health status and exposure to risk factors was obtained from face-to-face interviews conducted in the subject’s native language by trained and certified staff. Questions were derived from the 1978 ATS Epidemiology Standardisation Project,\textsuperscript{17} the European Community Respiratory Health Survey,\textsuperscript{18} the Consilio Nazionale Ricerche study,\textsuperscript{19} and the Obstructive Lung Disease in North Sweden study.\textsuperscript{20}

National mortality data for 193 countries were obtained from the World Health Organization\textsuperscript{21} for two age groups, 15–59 and 60+ years, and expressed as rates/100 000 population. For each site we estimated for the age groups 40–59 years and 60+ years the prevalence of airflow obstruction and the prevalence of spirometric restriction using sampling weights to account for the sampling strategies in each site.

We compared the national COPD mortality rates against the prevalence of airflow obstruction and of spirometric restriction in the BOLD centres using Spearman rank correlation. We then regressed the same mortality rates against the gross national income (GNI) per person for the country using data from the World Bank and expressed as US dollars (US$) adjusted for purchasing power parity (PPP)\textsuperscript{22} and the age-standardised national prevalence of cigarette smoking obtained from the Tobacco Atlas.\textsuperscript{23}

We finally regressed the prevalence of airflow obstruction and spirometric restriction against the mean pack years smoked in the site and against the GNI\textsuperscript{22} and plotted the results.

We do not expect the variance of the regression errors to be equal across observations (homoscedasticity) because the outcome and predictor variables in the regression models reflect ‘means’ of variables (rather than individual observations) from populations that vary in size. Therefore we used weighted least squares regression for which the weight is the population.\textsuperscript{24} The bigger the population the smaller the variance of the regression errors. In the models for national mortality data, the weight is the total number of men and women in the relevant age group in each country. In the regression models for prevalence of airflow obstruction and spirometric restriction, the weight is the total number of people with acceptable spirometry data in each site. For each model fitted residuals were plotted against the predicted values to investigate linearity of associations. When associations were not linear we transformed the predictor variable. When looking at the relationships between national mortality levels from COPD and GNI we used log GNI as the predictor variable whereas when looking at the relationship between spirometric restriction and GNI, we used 1/GNI.

To test the robustness of our findings to missing data, we reran the analyses involving data from the BOLD sites after excluding those sites that had a cooperation rate of less than 60%.

All analyses were done using Stata V.12 (Stata Corporation, College Station, Texas, USA). The correlation coefficients quoted are Spearman’s rank correlation coefficients (rs). If appropriate, robust SEs were computed to take account of any clustering within countries. Ethical approval was obtained by each site from the local ethical committee and written informed consent was obtained from every participant.

RESULTS
The sampling design used at each BOLD site is presented in online supplementary table E1 together with information on response and cooperation rates at each site. A third of the sites had cooperation rates above 80%, a third between 60% and 79% and a third below 60%. Low and middle income countries and Nordic countries had the highest cooperation rates.

The estimated prevalence of airflow obstruction aged 40 years and over ranged among men from 5.7% (Pune, India) to 23.0% (Cape Town, South Africa), and among women from 4.2% (Nampicuan, The Philippines) to 20.7% (Uppsala, Sweden) (table 1). The prevalence of spirometric restriction was much more variable, ranging among men from 8.4% (Bergen, Norway) to 67.7% (Mumbai, India) and among women from 6.7% (Bergen, Norway) to 70.5% (Srinagar, India).

The national mortality rates attributed to COPD in those aged 15–59 years were strongly correlated with the local prevalence of spirometric restriction in the BOLD sites in those aged 40–59 (men: rs=+0.73, p=0.0001; women rs=+0.90, p \leq 0.0001) but not with the prevalence of airflow obstruction (men: rs=+0.28, p=0.2; women: rs=+0.17, p=0.46). Similarly the national mortality rates attributed to COPD in those aged 60+ years were strongly correlated with the local prevalence of spirometric restriction in the BOLD sites in those over 60 years old (men: rs=+0.63, p=0.0022; women: rs=+0.37, p=0.1) but not with

Table 1  Number of participants included, prevalence of airflow obstruction (FEV1/FVC<LLN) and low FVC (<LLN) and mean pack years smoked from the BOLD sites for men and women separately, and GNI/capita (US PPP) and national smoking rates for men and women for countries containing BOLD sites.

BOLD, Burden of Obstructive Lung Disease; FEV1, forced expiratory volume in 1 s; FVC, forced vital capacity; GNI, gross national income; LLN, lower limit of normal; PPP, purchasing power parity.
the prevalence of airflow obstruction (men: \( r_s = +0.28; p=0.23 \); women: \( r_s = +0.22, p=0.33 \)).

Plots of COPD mortality rates for the 179 countries with available data showed a strong inverse association with GNI, with rates rising rapidly as GNI fell below US$15 000 per capita per annum (figure 1A) and showed no clear positive association with the age standardised prevalence of cigarette smoking in the 135 countries with available data (figure 1B).

Regression of national mortality rates from COPD against the logarithm of the GNI showed a strong negative association for both sexes and for both age groups (15–59 years and 60+ years) (\( p<0.001 \) in all cases) (table 2). For the 19 countries with BOLD data this association was qualitatively similar, though the regression coefficients were stronger (table 2).

Table 2 also shows the results of regressing mortality rates from COPD against national smoking rates. Coefficients are significantly negative for both age groups and both sexes. When this analysis was repeated using the local estimates of mean cumulative pack years smoked by the whole population in the 22 BOLD sites there was also a significant negative association in all groups with more smoking being associated with a lower national mortality rate for COPD (table 2).

Although mortality from COPD was negatively associated with smoking, whether measured as the national age-standardised prevalence or as the local mean cumulative pack years smoked, there was a clear positive association between the prevalence of airflow obstruction and the mean pack years smoked in the 22 BOLD sites (figure 2A) accounting for 37% of the variance in men (\( p=0.003 \)) and 35% of the variance in women (\( p=0.004 \)) (table 3). The prevalence of airflow obstruction increased by 4.0% per 10 pack years smoked in men and by 6.7% per 10 pack years in women. The association between prevalence of airflow obstruction and GNI was weakly positive but not significant (men: \( p=0.78 \); women \( p=0.06 \)) (figure 2B; table 3).

Table 3 also shows that spirometric restriction was slightly more common when smoking rates were higher, an association that was statistically significant for women (\( p=0.021 \)) but not for men (\( p=0.071 \)) (figure 3A; table 3). There was, however, a strong association between the prevalence of spirometric restriction and a lower GNI (men \( p<0.001 \); women \( p<0.001 \)) with rates rising rapidly as GNI fell below US$15 000/capita/annum (table 3; figure 3B).

When we reran the analyses reported in tables 2 and 3 after excluding the BOLD sites that had a cooperation rate of less than 60% the associations that we found were qualitatively similar to those using all the sites (see online supplementary tables E2 and E3).

**DISCUSSION**

The poor correlation between mortality rates from COPD and the prevalence of smoking has been remarked on before at the national and international level, but the findings from BOLD go further in showing that smoking is a good predictor of the prevalence of airflow obstruction. Other causes of airflow obstruction, such as biomass exposure, are not therefore required to explain any discrepancy between the prevalence of obstruction and the prevalence of smoking.

The strong relation of COPD mortality with poverty has also been described at a national level, and in England and Wales the social class gradient for COPD mortality is steeper than for either lung cancer or even tuberculosis. The implications for global health, however, have not been widely understood. Nor has the similarity of the global distributions of COPD mortality and the prevalence of spirometric restriction or their relation to the per capita GNI.

The prevalence of airflow obstruction correlates well with the mean pack years smoked in the BOLD sites and with national estimates of the prevalence of smoking. However, the national...
mortality rates from ‘COPD’ do not correlate with either the national prevalence of smoking or with the local prevalence of airflow obstruction. However, they do correlate well with the prevalence of spirometric restriction. Both ‘COPD’ mortality rates and the prevalence of spirometric restriction are strongly associated with the GNI per head of population, each rising steeply as GNI/capita falls below US$15 000 PPP.

Although we do not yet have direct evidence from the BOLD study, evidence from the USA shows that the FVC is a much stronger determinant of survival than the FEV₁/FVC ratio.

Table 2  Association of national mortality levels from COPD with logarithm of GNI/capita ($US PPP) for all 179 countries with information and for the 19 countries with BOLD sites, and age-adjusted national smoking prevalence for 135 available countries and with mean pack years smoked for 22 BOLD sites

BOLD, Burden of Obstructive Lung Disease; COPD, chronic obstructive pulmonary disease; GNI, gross national income; PPP, purchasing power parity.

Figure 2  Prevalence of airflow obstruction (FEV₁/FVC<LLN) by sex and (A) mean pack years smoked and (B) annual per capita gross national income. FEV₁, forced expiratory volume in 1 s; FVC, forced vital capacity; LLN, lower limit of normal; PPP, purchasing power parity.
‘COPD’ is defined in terms of chronic airflow limitation but this definition has its limitations and in surveys the association between self-reported ‘COPD’ and airflow obstruction is weak. Given that very few people will have had spirometry, this discrepancy is unsurprising. In addition, given the difficulty in ante-mortem diagnosis, it is understandable if those with spirometric restriction and without airflow obstruction are certified as having died of ‘COPD’.

The BOLD project is the largest and most ambitious attempt to date to quantify the global variation in ventilatory function with associated symptoms and risk factors. The quality of lung function data from the BOLD study is controlled at a high level. All technicians were trained according to a common protocol and all the spirometric tracings were checked centrally for quality during the fieldwork and errors fed back to the technicians. When readings were inadequate, technicians were suspended until they had been retrained. Spirometry that did not reach ATS/ERS standards was rejected. Estimates of deaths by cause were taken from the Global Health Observatory of the World Health Organization and were calculated using methods summarised elsewhere.

In some BOLD sites the estimates of prevalence are based on studies with relatively low response rates, but when we omitted all sites with a cooperation rate below 60%, the results did not materially change. There are very few data missing from national sources and those that are missing are generally from small countries. The main exceptions are a small number of large countries, such as the USA, Germany and Australia with missing smoking data. This small number of missing units is unlikely to make any difference to the results.

In comparing data from the BOLD sites with national data on smoking, income or mortality we are making an assumption that the sites are representative of their country. Formally this is not the case, but the assumption is nevertheless not

BOLD, Burden of Obstructive Lung Disease; FEV1, forced expiratory volume in 1 s; FVC, forced vital capacity; GNI, gross national income; LLN, lower limit of normal; PPP, purchasing power parity.

Figure 3 Prevalence of a spirometric restriction (FVC<LLN) by (A) mean pack years smoked and (B) annual per capita gross national income. FVC, forced vital capacity; LLN, lower limit of normal; PPP, purchasing power parity.
Tobacco is the highest ranked risk factor for disease burden in high-income North America and Western Europe and second only to high blood pressure globally according to the most recent estimates. Nevertheless, in low-income countries other factors associated with poverty dominate the risk of mortality attributed to ‘COPD’, even though spirometrically measured chronic airflow obstruction remains overwhelmingly a condition associated with smoking in all regions. There is a serious danger that an epidemic of smoking, if ever it were to become established in these vulnerable regions, would have even more devastating effects than we have seen so far in the more affluent countries.

It is unlikely that the high mortality attributed to ‘COPD’; particularly in low-income countries, is associated with chronic airflow obstruction. It is much more likely to be associated with spirometric restriction. These analyses challenge us to rethink our notions and beliefs about the origins and significance of chronic lung disease and its prominent role as a major cause of death in low-income countries. This by no means reduces the importance of tobacco control as the most important approach to the prevention of chronic airflow obstruction and other morbidity.

**Collaborators**

Research teams at centres: NanShan Zhong (PI), Shengming Liu, Jiechun Lu, Poon R. D. Wei, Dali Wang, Jingjing Zheng, Yunmin Zhou (Guangzhou Institute of Respiratory Diseases, Guangzhou Medical College, Guangzhou, China); Ali Kocaba (PI), Attila Hancioglu, Jasper Freeman, Anton Hayes, Sipho Hlatshwayo, Christine Johannisen, Mariana Koopman, Innocentia Louw, Ina Ludick, Alta Ockers, Johanna Ryck, Janita Storbeck, (University of Cape Town Lung Institute, Cape Town, South Africa); Thorarinn Gislason (PI), Bryndis Benediktsdottir, Kristin Jorundsdottir, Lovisa Gudmundsdottir, Sigrun Gudmundsdottir, Gunnar Gundmundsdottir (Landspitali University Hospital, Department of Chest Diseases, Adana, Turkey); Michael Studnicka (PI), Torkil Davidsen, Bernd Lamprecht, Lea Schiifoer (Paracelsus Medical University, Department of Pulmonary Medicine, Salzburg Austria); Eric Bateman (PI), Amanka Jithoo (PI), Deseree Adams, Edward Barnes, Jasper Freeman, Anton Hayes, Sipho Hlatshwayo, Christine Johannisen, Mariana Koopman, Innocentia Louw, Ina Ludick, Alta Ockers, Johanna Ryck, Janita Storbeck, (University of Cape Town Lung Institute, Cape Town, South Africa); Thorarinn Gislason (PI), Bryndis Benediktsdottir, Kristin Jorundsdottir, Lovisa Gudmundsdottir, Sigrun Gudmundsdottir, Gunnar Gundmundsdottir (Landspitali University Hospital, Department of Allergy, Respiratory Medicine and Sleep, Reykjavik, Iceland); Ewa Nizankowska-Mogilnicka (PI), Jakub Frey, Rafal Harat, Filip Mejza, Pawel Nastalek, Andrzej Pajak, Wojciech Skucha, Andrzej Szczeklik, Małgorzata Twardowska (Division of Pulmonary Diseases, Department of Medicine, Jagiellonian University School of Medicine, Cracow, Poland); Tobias Welte (PI), Isabelle Bodemann, Henning Geldmacher, Alexandra Schweba-Linow (Hannover Medical School, Hannover, Germany); Amund Guldvik (PI), Tina Erdensle, Lene Swendsen (Department of Thoracic Medicine, Institute of Medicine, University of Bergen, Bergen, Norway); Wan C Tan (PI), Wen Wang (ICapture Center for Cardiovascular and Pulmonary Research, University of British Columbia, Vancouver, BC, Canada); David M Mannino (PI), John Cain, Rebecca Copeland, Dana Hazen, Jennifer Methvin (University of Kentucky, Lexington, Kentucky, USA); Renato B Dantes (PI), Lourdes Amarillo, Lakan U Berratio, Benjamin Hardaker, Brett Toelle (Woolcock Institute of Medical Research, Sydney, Australia); Peter G J Burney (PI), Carol Amor, James Potts, Michael Tumility, Fiona McLean (National Heart and Lung Institute, Imperial College, London); E F M Wouters, Burney P, et al. Thorax 2014;69:465–473. doi:10.1136/thoraxjnl-2013-204460
Respiratory epidemiology

G J Wensing (Maastricht University Medical Center, Maastricht, The Netherlands); Cristina Bárbara (PI), Fátima Rodrigues, Herminia Dias, João Cardoso, João Almeida, Maria João Matos, Paula Simão, Moutinho Santos, Reis Ferreira (The Portuguese Society of Pneumology, Lisbon, Portugal); Chistier Janson (PI), Inga Sif Olafsdottir, Katarina Nisser, Ulrike Spetz-Nyström, Gunn-Helge Pham and Gun-Marie Lund (Department of Medical Sciences: Respiratory Medicine & Allergology, Uppsala University, Sweden); Rain Jögi (PI), Hendrik Laja, Katri Utas, Vappu Zobel, Toomas-Julius Lill (Lung Clinic, Tartu University Hospital); Parvaz A Kouli (PI), Sajjad Malik, Nassar A Hakim, Umar Halef Khan (Sher-i-Kashmir Institute of Medical Sciences, Srinagar, J&K, India); Rohini Chowgule (PI) Vasant Shetye, Jontelle Raphael, Rupali Endrade, Mahadevi Sanyal, Raffag Tatj, Sumedh Kulkarni, Sunil Bhonsle, Uddhav Dhanawade, Umesh Gharpur (Indian Institute of Environmental Medicine, Mumbai, India); Imed Harrabi (PI), Myrni Denguelli, Souhail Tabka, Hager Daldoul, Zaki Boucherkoufa, Firas Choukhia, Wabeh Belhaj Khalifa (Faculté de Médecine, Sousse, Tunisia); Luisito F Eldor (PI), Teresita S de Guio, Norberto A Francisco, Camilo C Roa, Fernando G Ayauyo, Cezil T Dady, Daniel T Tan, Sylvia Banal-Yang, Vincent M Balanag, Jr, Maria Teresa N Reyes, Renato B Dantes (Lung Centre of The Philippines, Philippine General Hospital, Nampicuan&Talugtug, The Philippines); Sundeep Salvi (PI), Sundep Salvi (PI), Siddhi Hirve, Bill Brassher, Jiyot Londo, Sapna Madas, Somnath Sambhudas, Bharat Chaidhary, Meera Tambe, Savita Pingale, Arati Umap, Archana Umrit, Nitin Shelar, Sampada Devchakka, Sharda Chaudhury, Suvarna Bondre, Savita Walkle, Ashlesha Gawhane, Anil Sapkal, Rupali Argade, Vijay Gokhale (Vadu HDSS, KEM Hospital Research Centre Pune, Chest Research Foundation (CRF), Pune, India); In the first phase of the study, Dr O R Crapo and Dr R J Jensen (LDS Hospital, Salt Lake City, Utah, USA) were responsible for quality assurance of lung function; they and Dr Paul Enright (University of Arizona, Tucson, Arizona, USA) and Georg Harnoncourt (Medizinzentrum AG, Zurich, Switzerland), provided lung function services.

Contributors SB, WMV, PB, were engaged in the initial design of the study. BK analysed the data. LG coordinated the later part of the study and AJ quality assured the lung function data for the second part of the study. All the other authors involved in the AJ, managed centres that collected data. PB drafted the initial manuscript, and all authors contributed to its development and approved the final version.

Funding The BOLD Study is funded by a grant from the Wellcome Trust (085790/2/08/2). The initial BOLD programme was funded in part by unrestricted educational grants to the Operations Center in Portland, Oregon from ALATA, Aventis, AstraZeneca, Boehringer-Ingelheim, Chiesi, GlaxoSmithKline, Merck, Novartis, Pfizer, Schering-Plough, Sepracor, and the University of Kentucky. Additional local support for BOLD sites was provided by Boehringer Ingelheim China (Guangzhou, China); Turkish Thoracic Society, Boehringer-Ingelheim and Pfizer (Adana, Turkey); AlZta, Astra-Zenaeca, Boehringer-Ingelheim, GlaxoSmithKline, Merck Shapre & Dohme, Novartis, Salzburger Gebietskrankenkassen and Salzburg Local Government (Salzburg, Austria); Research for International Tobacco Control, the South African Medical Research Council, the South African Thoracic Society GlaxoSmithKline Pulmonary Research Fellowship; AK, IH, TG, CK, EB, PB, SA–A and LG have nothing to disclose.

Ethics approval This study required local ethical approval.

Provenance and peer review Not commissioned; externally peer reviewed.

Data sharing statement The data from the BOLD Study are not generally available. But we do share data, with the agreement of the contributors, to achieve specific objectives.
